#### Abstract

The presence of two ( $4 n+2$ )-electron conjugated systems in perpendicular planes results in considerable aromatic stabilization. Despite having two fewer hydrogens, the $6 \pi \mathrm{e}-2 \sigma \mathrm{e} 3,5$-dehydrophenyl cation $\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{+}, \mathbf{1}\right)$ is 32.7 (CCSD(T)/6-31G**) and $35.2 \mathrm{kcal} / \mathrm{mol}$ (RMP4sdtq/6-31G*//RMP2(fu)/6-31G*) more stable than the phenyl cation (evaluated by an isodesmic reaction involving benzene and $m$-dehydrobenzene (4)). Cation $\mathbf{1}$, the global $\mathrm{C}_{6} \mathrm{H}_{3}{ }^{+}$ minimum, is $11.7,24.2,11.8$, and $30.4 \mathrm{kcal} / \mathrm{mol}$ lower in energy than the $2,6-(\mathbf{1 1})$ and 3,4 -dehydrophenyl (12) cations as well as the open-chain isomers $\mathbf{1 3}$ and $\mathbf{1 4}$ (RMP4sdtq/6-31G*//RMP2(fu)/6-31G* + ZPE(RMP2(fu)/6-31G*)). The stability of $\mathbf{1}$ is increased hyperconjugatively by $2,4,6$-trisilyl substitution. The double aromaticity of $\mathbf{1}$ is indicated by the computed magnetic susceptibility exaltations (IGLO/II//RMP2(fu)/6-31G*) of $-5.2,-6.8,-15$, and -23.2 relative to $\mathbf{1 1}, \mathbf{1 2}, \mathbf{1 3}$, and $\mathbf{1 4}$, respectively. Thus, 1 fulfills the geometric, energetic, and magnetic criteria of aromaticity. The double aromaticity of the $D_{6 h}$ cyclo[6]carbon is apparent from the same criteria.

## Introduction

Besides having the conventional $6 \pi$ electron aromaticity, the 3,5-dehydrophenyl cation (1) is stabilized by three-center twoelectron (3c-2e) bonding (1a) in the ring plane ("in-plane aromaticity"). ${ }^{1}$ This "doubly aromatic" cation (1), first conceived in $1979,{ }^{1}$ is a minimum at HF/STO-3G and was computed (isodesmic reaction 1) to be stabilized relative to the phenyl cation (3) and 1,3-dehydrobenzene (4) by 14.4 (HF/4-31G//HF/STO3G) and $38.5 \mathrm{kcal} / \mathrm{mol}$ (MINDO/3).

Occupied molecular orbitals resulting from in-phase overlap of three p (or $\mathrm{sp}^{n}$ ) atomic orbitals stabilize molecules. The $\pi$-aromatic cyclopropenyl cation, $(\mathrm{CH})_{3}{ }^{+}(5)$, with three parallel $p(\pi)$ orbitals, is the best known example of $3 \mathrm{c}-2 \mathrm{e}$ bonding. ${ }^{2}$ The three overlapping p orbitals are tilted inwards in the trishomocyclopropenium ion (6). In three-membered rings, a lowlying MO is comprised of three in-plane radial-type p (really sp) orbitals which overlap in the center (7) and result in $3 \mathrm{c}-2 \mathrm{e}$ $\sigma$-bonding. In cyclopropane, this "surface delocalization" contributed to " $\sigma$-aromaticity"."-5

[^0]

Fukunaga et al. ${ }^{6}$ suggested the possibility of analogous "trefoil" $3 \mathrm{c}-2 \mathrm{e}$ bonding in other systems with $\pi$ perimeters. Stabilization can be expected when the $\sigma$ centers are close together, e.g., in [5.5.5]trefoilene, $\mathrm{C}_{9} \mathrm{H}_{6}(8)$. A double aromatic $10 \pi$ electron structure with the trefoil $3 \mathrm{c}-2 \mathrm{e}$ bond might be achieved if one $\sigma$ electron were shifted into the $\pi$ system. Whereas MINDO/3 and MNDO calculations do show that the electronic structure of 8 conforms to this possibility and that the CC bond length alternation is small, the same calculations reveal that $\mathbf{8}$ is not a minimum and is highly unstable. The valence isomer of 8 , cyclonona-1,2,4,5,7,8-hexaene (8a), favors a nonplanar $D_{3}$ geometry and is nearly $100 \mathrm{kcal} / \mathrm{mol}$ lower in energy than $8 .^{7}$

8. $D_{3 n}$

80, $D_{3}$

9, $D_{4 n}$

10, $D_{\text {sh }}$

Our earlier computational searches for structures exhibiting double aromaticity due to homoconjugative overlap of radially oriented $\mathrm{p}_{\sigma}\left(\mathrm{sp}^{n}\right)$ orbitals also did not succeed. For example, neither the $D_{4 h}$ form of the hypothetical $\mathrm{C}_{8} \mathrm{H}_{4}$ hydrocarbon 9 (which might have $10 \pi$ and $4 \mathrm{c}-2 \mathrm{e} \sigma$ central arrangement) nor the $\mathrm{C}_{10} \mathrm{H}_{5}-$ $D_{5 h}$ anion 10 (with $10 \pi$ and $5 \mathrm{c}-6 \mathrm{e} \sigma$ systems) appears to be stabilized when examined computationally. ${ }^{8}$

The possible experimental detection of $1^{9}$ has encouraged us to report this reexamination at more sophisticated ab initio levels. Is 1 a minimum? What is its stabilization energy? Is 1 more stable than other $\mathrm{C}_{6} \mathrm{H}_{3}{ }^{+}$cyclic and open-chain isomers, e.g., 1114? Does 1 have double aromatic character? How can this be demonstrated?

## Calculation Methods

Using the GAUSSIAN 92 program, ${ }^{10 a}$ the geometries of 1-4 and 11-14 were optimized at RMP2(fu)/6-31G*. The larger, silyl-substituted systems 18 and 19 (discussed later) were optimized only at RHF/6-31G* and 21-24 at RMP2(fc)/6-31G*. ${ }^{*} 112$ Single-point energies were computed at RMP4sdtq(fc)/6-31G* ${ }^{13}$ using the RMP2(fu)/6-31G* geometries. Analytical second derivatives established the nature of all stationary points at the RMP2(fu)/6-31G* level (18 and 19 at RHF/

6-31G*). ${ }^{14}$ These are indicated by the number of imaginary frequencies (NIMAG), e.g., NIMAG $=0$ for minima and NIMAG $=1$ for transition states. ${ }^{12}$ Zero-point vibrational energies (ZPEs), all scaled by the average factor $0.91,{ }^{15}$ are used to correct the relative energies (Table 1). Natural population analysis (NPA) ${ }^{16}$ was used to probe the electronic structure of 1 (Table 2). The "doubly aromatic" character of 1 was assessed by comparing its magnetic susceptibility, computed with the IGLO method using the standard II basis set ${ }^{17}$ and the correlated geometries (IGLO/ II/RMP2(fu)/6-31G ${ }^{*}$ ), with those of the other $\mathrm{C}_{6} \mathrm{H}_{3}{ }^{+}$isomers, 11-14 (Table 3). In selected cases, $\operatorname{CCSD}(\mathrm{T}) / 6-31 \mathrm{G}^{* *}{ }^{13 b}$ calculations have been carried out with the ACES II program ${ }^{10 \mathrm{~b}}$ to test the reliability of the MP4 results. MP4 is known to overestimate triple effects because of the absence of TT coupling terms as this level of theory. ${ }^{13 \mathrm{c}, \mathrm{d}} \mathrm{CCSD}(\mathrm{T})$ includes a number of these terms at MP6 and higher levels and, therefore, gives a balanced account of $T$ correlation effects. Also, it covers a significant part of multireference effects and, accordingly, is more reliable than MP4. By computing the singlet-triplet splitting in 1, 11, and 12, the calculations were carried out at the Becke3LYP/6-31G* level of the

density functional theory using the G92/DFT program. ${ }^{100}$ Although from our experience the structure parameters from the MP2 and Becke3LYP levels are usually quite similar, the Becke3LYP-DFT includes the effects of both dynamic and nondynamic correlation to some extent, and the calculated vibrational frequencies are in good agreement with the measured values. Thus, no scalation is necessary for the ZPE estimations.

## Results and Discussion

The $D_{3 h}$ structure 1 is a minimum at RMP2(fu)/6-31G* (the lowest frequency, $\nu\left(a_{2}{ }^{\prime \prime}\right)=433 \mathrm{~cm}^{-1}$, is quite large). The CC ring bond lengths (all $1.366 \AA$ ) at both MP2 and $\operatorname{CCSD}(\mathrm{T})$ are substantially shorter than those in benzene (1.395 (MP2) and $1.400 \AA$ (CCDS(T), Figure 1 in italics). The bare carbons, C1, C 3 , and C 5 , are closer to the center of the ring ( $1.177 \AA$ ) than the CH carbons ( $1.498 \AA$ ) (Figure 1). The MP2 central C1C3, C 3 C 5 , and $\mathrm{C1C5}$ distances, $2.038 \AA$ (cf. the MINDO/ 3 value, $2.020 \AA),{ }^{1}$ are longer than the CCSD(T) values of $1.933 \AA$. This seems to indicate somewhat stronger through-space 1,3-interaction at the $\operatorname{CCSD}(\mathrm{T})$ level than at the MP2 level.

The cyclic isomers 11 and 12 also are minima but are 11.7 and $24.2 \mathrm{kcal} / \mathrm{mol}$ higher in energy than 1, respectively (RMP4sdtq/ 6-31G*//RMP2(fu)/6-31G* + ZPE(RMP2(fu)/6-31G*). At the same level, the open-chain isomers 13 and 14 (Figure 2) are 11.8 and $30.4 \mathrm{kcal} / \mathrm{mol}$ higher in energy than 1 , respectively (Table 1). Thus, 1 appears to be the $\mathrm{C}_{6} \mathrm{H}_{3}{ }^{+}$global minimum.

The isodesmic ${ }^{12}$ reaction energy (eq 1), $32.7 \mathrm{kcal} / \mathrm{mol}$ at CCSD(T) $/ 6-31 \mathrm{G}^{* *}$ and $35.2 \mathrm{kcal} / \mathrm{mol}$ at RMP4sdtq $/ 6-31 \mathrm{G}^{*} / / \mathrm{MP} 2 /$ $6-31 \mathrm{G}^{*}$, is closer to the earlier MINDO $/ 3$ value ( $38.5 \mathrm{kcal} / \mathrm{mol}$ ) and larger than that computed at STO-3G. ${ }^{1}$ All the molecules, $1-4$, in eq 1 are $6 \pi$ electron systems. The shortest $1,3-C C$ distances are $2.436 \AA$ in the phenyl cation (3) and $2.106 \AA$ (C1C3) in $m$-benzyne (4) at $\operatorname{CCSD}(\mathrm{T}) / 6-31 \mathrm{G}^{* *}$ (2.423 and $2.123 \AA$, respectively, at MP2). ${ }^{81}$ The average CC bond lengths ( 1.390 and $1.388 \AA$ at $\operatorname{CCSD}(\mathrm{T}), 1.385$ at MP2) in 3 and 4 are longer than the CC bond length in $1(1.366 \AA$ at both $\operatorname{CCSD}(\mathrm{T})$ and MP2) but are closer to the benzene value ( $1.400 \AA$ at $\operatorname{CCSD}(T)$, $1.395 \AA$ at MP2) (Figure 1). Reaction (eq 1) provides a basis to estimate the heat of formation for cation 1. Using the heat

16

17

The preferred structure of $m$-benzyne (4) deserves a more detailed comment. ${ }^{18}$ The bicyclic geometry 4 a (claimed on the basis of MNDO calculations to be a separate minimum with a $1.628 \AA \mathrm{ClC} 3$ distance, $5.7 \mathrm{kcal} / \mathrm{mol}$ higher in energy than 4) ${ }^{18 \mathrm{~b}}$ is also calculated at HF/6-31G* (erroneously) to be a minimum with a $1.483 \AA \mathrm{ClC} 3$ distance. However, in accord with GVB and MP2/6-31G** calculations on 2,4-didehydrophenol (15), ${ }^{19}$ bicyclic 4a does not survive GVB, MP2, or MP4/6-31G** 18 e optimizations and is converted into 1,3 -dehydrobenzene ( m benzyne) (4) (the C1C3 distance elongates to $2.106 \AA$ ) (Figure 1). TCSCF and MCSCF calculations by Borden et al. ${ }^{18 c}$ and by Squires et al. ${ }^{18 \mathrm{~d}}$ gave similar results: 4 a is $12-15 \mathrm{kcal} / \mathrm{mol}$ higher in energy than 4 (TCSCF/6-31G* and $\operatorname{MCSCF}(2,2) / 6-31 G^{*}$ using the RHF geometries). TCSCF and MCSCF optimizations, starting from the RHF geometries for 4 a , both led back to 4.

Equal or nearly equal ring bond lengths-the geometric criterion of aromaticity-is one of the characteristics of an aromatic molecule..$^{20-23}$ On this basis, 1 , with a CC bond length

[^2]of $1.366 \AA$, should possess greater aromatic character than 3 and 4 with nonequal $C C$ bond lengths. ${ }^{20-23}$ The Wiberg bond indexes (WBIs ${ }^{24}$ ) for ClC 2 and ClC 3 in 1 are 1.447 and 0.376 , respectively; these may be compared with the benzene values of 1.440 and 0.113 (Table 2). Hence, electron delocalization embracing the $\mathrm{C1C3C} 5$ triangle is present in 1 , notwithstanding the rather long C1C3, C3C5, and C1C5 distances. Such electron delocalization, resulting from orbital overlap without supporting the CC bond, is exemplified by the homotropylium cation (16), with a C1C7 distance of $1.906 \AA$ at RMP2(fu)/6-31G* ${ }^{25}$ ( 2.031 $\AA$ at RMP4sdq//RMP2(fu)/6-31G*) ${ }^{26}$ and by the 1,3 -dehy-droadamant-5,7-diyl dication (17), with its $2.084 \AA$ C1C3distance at RMP2(fu)/6-31G*, ${ }^{25}$ as well as by the trishomocyclopropenium ion (6), with its ClC 3 distance of $1.842 \AA$ at RMP2(fu)/6$31 G^{*}{ }^{25}$ Apart from stabilizing through-space interactions and resulting 2-electron delocalization, cation 1 can also benefit from through-bond interactions involving the radially oriented $\sigma$ orbitals at $\mathrm{C} 1, \mathrm{C} 3$, and C 5 and the $\sigma^{*}$ orbitals of the six-membered ring. Such interactions have been found to be stabilizing factors in $m$-benzyne, where they lead to additional electron pairing possibilities for the singlet biradical. ${ }^{18 a, d, e}$
The C2, C4, and C6 carbons in 1 bear negative natural charges $(-0.323)$ which are counterbalanced by the positive hydrogen charges ( 0.336 ) according to NBO analysis. ${ }^{16}$ The bare carbons, $\mathrm{C} 1, \mathrm{C} 3$, and C 5 , involved in the three-center interaction share the remaining net positive charge ( +0.321 each). This charge alternation on the carbons may lead to additional stabilization. ${ }^{27}$ While the $D_{3 h}$ symmetric 3,5 -dehydrophenyl cation (1) fulfills the geometric and energetic criteria of aromaticity, these characteristics are absent and not well in 11, 12, 13, and 14, since 11 and 12 are 11.7 and $24.2 \mathrm{kcal} / \mathrm{mol}$ less stable than 1 at the RMP4sdtq/6-31G*//RMP2(fu)/6-31G* + ZPE(RMP2/631G*) level.

About 25 years ago, Dauben et al. ${ }^{28}$ used the exaltation of magnetic susceptibility to characterize aromatic systems. Exaltation of the magnetic susceptibility ( $\Lambda$ ) characterizes an "aromatic" compound. This magnetic susceptibility exaltation has been attributed to the presence of cyclic delocalization of electrons ("ring current"). Cremer et al. ${ }^{26,29}$ used this magnetic criterion to characterize the homo- and bishomoaromaticity in the homo- and bishomotropenylium cations as well as in the barbaralyl cation. Our group ${ }^{30,31}$ has used the same criterion to demonstrate the aromaticity of pericyclic transition states. Generally, $\Lambda$ is defined as the difference between the measured bulk magnetic susceptibility value and the susceptibility evaluated on the basis of an increment system ( $\Lambda=\chi_{M}-\chi_{M^{\prime}}$ ). In this paper, the magnetic susceptibility exaltation values are the differences between the IGLO calculated magnetic susceptibilities for isomers.

We now characterize the double aromaticity in 1 by evaluating the magnetic susceptibility exaltation ( $\Lambda$ ). With IGLO/II// RMP2(fu)/6-31G*, ${ }^{17}$ the calculated magnetic susceptibilities ( $\chi_{\text {tot }}, \mathrm{ppm} \mathrm{cgs}$ ) are 1, $-61.5 ; 11,-56.3$; and 12, -54.7 . For the

Figure 3. RHF/6-31G* geometries of $\mathbf{1 8}$ (2,4,6-trisilyl-3,5-dehydrophenyl cation) and 19 (2,4,6-trisilylphenyl cation).
open-chain isomers 13 and 14, the $\chi_{\text {tot }}$ values are -46.5 and -38.3 , respectively. Thus, the magnetic susceptibility exaltations for 1 are -5.2 and -6.8 , in comparison with the cyclic isomers 11 and 12 (which have $6-\pi$-electron systems). Larger values, -15.0 and -23.2 , are found for the acyclic isomers 13 and 14. Hence, the 3,5-dehydrophenyl cation (1) fulfills the magnetic as well as the geometric and energetic criteria of aromaticity. In comparison with the open-chain isomers 13 and 14 , the cyclic isomers 11 and 12 should have partial aromatic character from the same criterion. Even the more negative magnetic susceptibility anisotropies, -94.2 (1), -47.8 (11), -41.6 (12), -20.5 (13), and -37.0 (14), indicate the aromaticity of 1 and partial aromaticity of 11 and 12 (Table 3 ). The larger magnetic susceptibility anisotropy ( -94.2 ) and magnetic susceptibility exaltation ( -23.2 , relative to 14 ) in 1 , compared to the benzene values ( $\chi_{\text {anis }}=-62.9$ and $\Lambda=-13.4$ ), clearly reveal the doubly aromatic nature of 1 . The calculated ${ }^{1} \mathrm{H}$ chemical shift is 9.2 ppm , and $\delta\left({ }^{13} \mathrm{C}\right)$ is 206.2 for the bare carbon and 54.7 for the other carbons ( $\mathrm{C}-\mathrm{H}$ ).

Observation of 3,5-Dehydrophenyl Cations. While $\mathrm{C}_{6} \mathrm{H}_{3}{ }^{+}$ions have been detected mass spectrometrically, ${ }^{9}$ their structures are unknown. Ongoing gas phase experiments may provide more decisive evidence. ${ }^{9}$ Can 3,5-dehydrophenyl cations be observed in solution? While the parent ion, $\mathbf{1}$, is appreciably more stable than the phenyl cation, detection in nonnucleophilic "superacid" media seems unlikely. However, appropriately substituted systems may be more promising.

Attempts to generate phenyl cations by solvolysis failed until it was appreciated that the $\beta$-silicon effect ${ }^{32}$ would lead to substantial $\mathrm{Si}-\mathrm{C}$ hyperconjugative stabilization, e.g., in the 2,6-di-SiR ${ }_{3}$ phenyl cation. ${ }^{33}$ This $\beta$-Si effect might also stabilize 1, e.g., by $2,4,6$-trisilyl substitution (18) (Figure 3). Indeed, the $\mathrm{HF} / 6-31 \mathrm{G}^{*}$ energies of isodesmic reactions 2 and 3 indicate

${ }^{a}$ The singlet-triplet energy gaps (Becke3LYP/6-31G** ZPE-(Becke3LYP/6-31G*)). ${ }^{b}$ Relative energies of the singlet states (Becke3LYP/6-31G* + ZPE (BEcke3LYP/6-31G*)). ${ }^{\text {c }}$ Relative energies of the triplet states (Becke3LYP/6-31G* + ZPE (Becke3LYP/6-31G*)).
cation 18 to have a stabilization energy ( $-19.9 \mathrm{kcal} / \mathrm{mol}$ ) similar to that of the trisilyl-substituted phenyl cation ( $-22.4 \mathrm{kcal} / \mathrm{mol}$ ) 19 (Figure 3, $\mathrm{X}=\mathrm{SiH}_{3}$ ).

Singlet-Triplet Splittings. Due to the pronounced biradical character of dehydrobenzene isomers, $18 \mathrm{a}, \mathrm{d}, \mathrm{e}$ it would be interesting to test the singlet-triplet splittings in 1, 11, and 12. For example, how high in energy is the degenerate pair of unoccupied antisymmetric $\sigma$ orbitals in 1? To what extent would the triplet state of 1 undergo Jahn-Teller distortion from $D_{3 h}$ symmetry, etc.? Geometry optimizations and energy calculations as well as characterizations of the singlet and triplet states for 1,11 , and 12 were carried out using the G920/DFT program at the Becke3LYP/6-31G* level of density functional theory (DFT). ${ }^{10 c}$ The optimized geometries are given in Figure 4, and the energies are given in Table 4. As given in Figure 4, the Becke3LYP/ 6-31G* CC separations (1.3-, 1.933; 1,2-, $1.358 \AA$ ) for singlet $\mathbf{1}$ (1S) are shorter than those at RMP2/6-31G* (2.038 and 1.366 $\AA$ ) and at $\operatorname{CCSD}(\mathrm{T}) / 6-31 \mathrm{G}^{* *}$ ( 1.982 and $1.366 \AA$, Figure 1). Hence, a stronger $\mathrm{C1C3C} 5$ triangle interaction in 1 is favored at Becke3LYP/6-31G* than at MP2/6-31G* or at $\operatorname{CCSD}(\mathrm{T})$ / $6-31 \mathrm{G}^{* *}$. The $D_{3 h}$ symmetric triplet 1 T is not an energy minimum rather than a transition state with two imaginary frequencies. The first frequency ( $-3551 \mathrm{~cm}^{-1}$ ) involves the carbon skeleton stretching to $C_{2 v}$ symmetry, and the second ( $-321 \mathrm{~cm}^{-1}$ ) pertains to ring twisting from $C_{2 v}$ to $C_{2}$. Indeed, $C_{2}$ symmetric 1TG is the triplet 3,5 -dehydrophenyl cation ground state. At Becke3LYP/ $6-31 \mathrm{G}^{*}+$ ZPE (Becke3LYP/6-31G*), 1T is $54.7 \mathrm{kcal} / \mathrm{mol}$ higher in energy than 1S, and the singlet-triplet energy gap ( $\Delta E_{\mathrm{ST}}$ ) between 1S and 1TG is $45.1 \mathrm{kcal} / \mathrm{mol}$ (Table 4). This is much larger than the $34.4 \mathrm{kcal} / \mathrm{mol} p$-benzyne value of Borden et al. ${ }^{18 \mathrm{c}}$ and ca. $36 \mathrm{kcal} / \mathrm{mol}$ of Squires et al. ${ }^{18 \mathrm{~d}}$ computed at various levels.
At Becke3LYP/6-31 $\mathrm{G}^{*}$, both the singlet and triplet states of 11 (11S and 11TG, $C_{2 v}$ ) and 12 (12S and 12TG, $C_{s}$ ) are energy minima. The large changes of the geometries are shown in Figure 4. The calculated $\Delta E_{\mathrm{ST}}$ values for $\mathbf{1 1 S} \rightarrow 11 \mathrm{TG}(27.3 \mathrm{kcal} / \mathrm{mol})$ and for $12 \mathrm{~S} \rightarrow 12 \mathrm{TG}(25.3 \mathrm{kcal} / \mathrm{mol})$ are smaller than the values for $\mathbf{1 S} \rightarrow \mathbf{1 T G}$. The energy differences between the singlet $1 \mathbf{S}$ and 11S and 12S are 2.3 and $15.6 \mathrm{kcal} / \mathrm{mol}$ (Table 4), which are 9.4 and $8.6 \mathrm{kcal} / \mathrm{mol}$ lower than the MP4 values (Table 1). On

$12 S, C_{s}$

$12 T G, C_{s}$

Figure 4. Becke3LYP/6-31G* geometries for the singlet (1S, 11S, 12S) and triplet (1T, 1TG, 11TG, 12TG) states of the $\mathrm{C}_{6} \mathrm{H}_{3}{ }^{+}$isomers.
the other hand, the triplet 11TG is lower in energy than both 1TG ( $15.5 \mathrm{kcal} / \mathrm{mol}$ ) and 12TG ( $11.2 \mathrm{kcal} / \mathrm{mol}$ ).

Double Aromaticity of Cyclo[6]carbon. Cyclo[6]carbon ${ }^{34}$ is another molecule with potential doubly aromatic character. Two pertinent isomers are possible, namely $21\left(D_{3 h}\right)$ and $22\left(D_{6 h}\right)$. As shown in Figure 5, the $D_{3 h} 21$, like 1, has in-plane three-center bonding with 1.333 and $1.809 \AA \mathrm{CC}$ bond lengths, whereas the $D_{6 h} 22$ has only one CC bond length of $1.324 \AA$. At RMP4SDTQ/ 6-31G*//RMP2/6-31G* + ZPE(RMP2/6-31G*), 22 is 0.5 $\mathrm{kcal} / \mathrm{mol}$ ( $2.6 \mathrm{kcal} / \mathrm{mol}$ without ZPE correction) more stable than 21. This means the three-center in-plane bonding stabilization, as in 1, does not compensate for the greater strain. In contrast to the earlier ab initio calculation ${ }^{34 \mathrm{a}}$ and the recent DFT result ${ }^{34 \mathrm{~d}}$ that 22 is a saddle point on the energy surface and higher in energy than 21, our calculations indicate that both 21 and 22 are energy minima (NIMAG $=0$, RMP2/6-31G*) and are nearly isoenergetic. This agrees well with the CASSCF/MRCI

[^4]

Figure 5. RMP2(fc)/6-31G* geomtries of cyclo[6]carbon in $D_{3 h}$ (21) and $D_{6 h}(22)$ symmetries as well as their $\mathrm{Li}^{+}$complexes $23\left(C_{30}\right)$ and 24 ( $C_{60}$ ).
calculations. ${ }^{34 e}$ The strong in-plane bonding of 22 is indicated by the Wiberg bond indexes (WBIs, Table 2). The C1C2 and $\mathrm{ClC4}$ WBIs of 22 ( 1.870 and 0.229 ) are larger than those for 21 (1.638 and 0.156 ) and for benzene ( 1.440 and 0.012). On the other hand, the calculated magnetic susceptibility and the magnetic susceptibility anisotropy for 22 ( -64.2 and -38.9 , respectively) are larger in magnitude than those for 21 ( -53.3 and -15.4). Hence, 22 is more "aromatic" than 21. Thus, 22 is the more favorable form of the cyclo[6]carbon according to the geometric, energetic, and magnetic criteria of aromaticity. ${ }^{20,22}$ The greater aromaticity of $\mathbf{2 2}$ relative to 21 is also indicated by the computed $\mathrm{Li}^{+}$upfield chemical shifts in the corresponding complexes 23 and 24. The delocalization in the carbon ring 24 leads to an upfield shift of the $\mathrm{Li}^{+}$cap ( -7.4 vs -4.2 in 23 ). ${ }^{35}$

[^5]
## Conclusions

The 3,5-dehydrophenyl cation (1) is $11.7,24.2,11.8$, and 30.4 $\mathrm{kcal} / \mathrm{mol}$ lower in energy respectively than its cyclic isomers, the 3,4- and 2,3-dehydrophenyl cations 11 and 12, and its open-chain isomers, 13 and 14 (RMP4sdtq/6-31G*//RMP2(fu)/6-31G* + ZPE(RMP2(fu)/6-31G*)). The effectiveness of the $1,3-$ stabilizing interactions in 1 , despite the rather long distances in the C1C3C5 triangle, is shown by the energy of isodesmic reaction, eq 1: the 3,5-dehydrophenyl cation (1) and benzene are 32.7 $\mathrm{kcal} / \mathrm{mol}$ more stable than the phenyl cation (3) and $m$-benzyne (4) $\left(\operatorname{CCSD}(\mathrm{T}) / 6-31 \mathrm{G}^{* *}\right)$. The heat of formation of cation 1 is predicted to be $343.9 \mathrm{kcal} / \mathrm{mol}$. While the term "aromaticity" may be overused, ${ }^{3,4,21,22,36} \mathrm{it}$ is appropriate to consider 1 to be a "doubly aromatic" species. In addition to the geometric and energetic criteria, the "double aromaticity" in $\mathbf{1}$ is demonstrated by the magnetic susceptibility exaltations of -5.2 and -6.8 , compared with its cyclic isomers 11 and 12 , respectively (which also have cyclic $6 \pi$ electron systems), as well as -15 and -23.2 , compared with the open-chain isomers 13 and 14 , respectively. The very large singlet-triplet energy gaps for the $\mathrm{C}_{6} \mathrm{H}_{3}{ }^{+}$cyclic isomers reveal that there are non singlet-triplet competitions. The greater aromaticity of the $D_{6 h}$ over the $D_{3 h}$ form of cyclo[6]carbon is indicated by the same criteria.

Acknowledgment. We thank R. Squires for information concerning his gas phase experiments on $\mathrm{C}_{6} \mathrm{H}_{3}{ }^{+}$cations, the Alexander von Humboldt Foundation for a Research Fellowship (M.N.G.), the Shanxi Normal University (People's Republic of China) for a fellowship (H. Jiao), and the UGC (New Delhi) and DAAD (Bonn) for support under an exchange program (J. Chandrasekhar), as well as the Deutsche Forschungsgemeinschaft, the Fonds der Chemischen Industrie, the Stiftung Volkswagenwerk, and the Convex Computer Corp. for support. Some of the calculations have been carried out on the CRAY Y-MP/464 of the Nationellt Superdatorcentrum (NSC), Linköping, Sweden. E. Kraka thanks the NSC for a generous allotment of computer time and the Swedish Natural Science Research Council (NFR) for financial support.
